INTRODUCTION AND OBJECTIVES

Molar Incisor Hypomineralisation (MIH) is a developmental enamel defect affecting permanent first molars and incisors. Given the pivotal role of dental officers in diagnosing and managing pediatric conditions, comprehensive knowledge and positive perceptions of MIH are essential for effective practice. This study aimed to assess the knowledge and perceptions of MIH among dental officers in Perak.

METHODOLOGY

This is a cross-sectional study using a validated, self-administered questionnaire involving 276 government primary dental officers across all 10 districts in Perak.

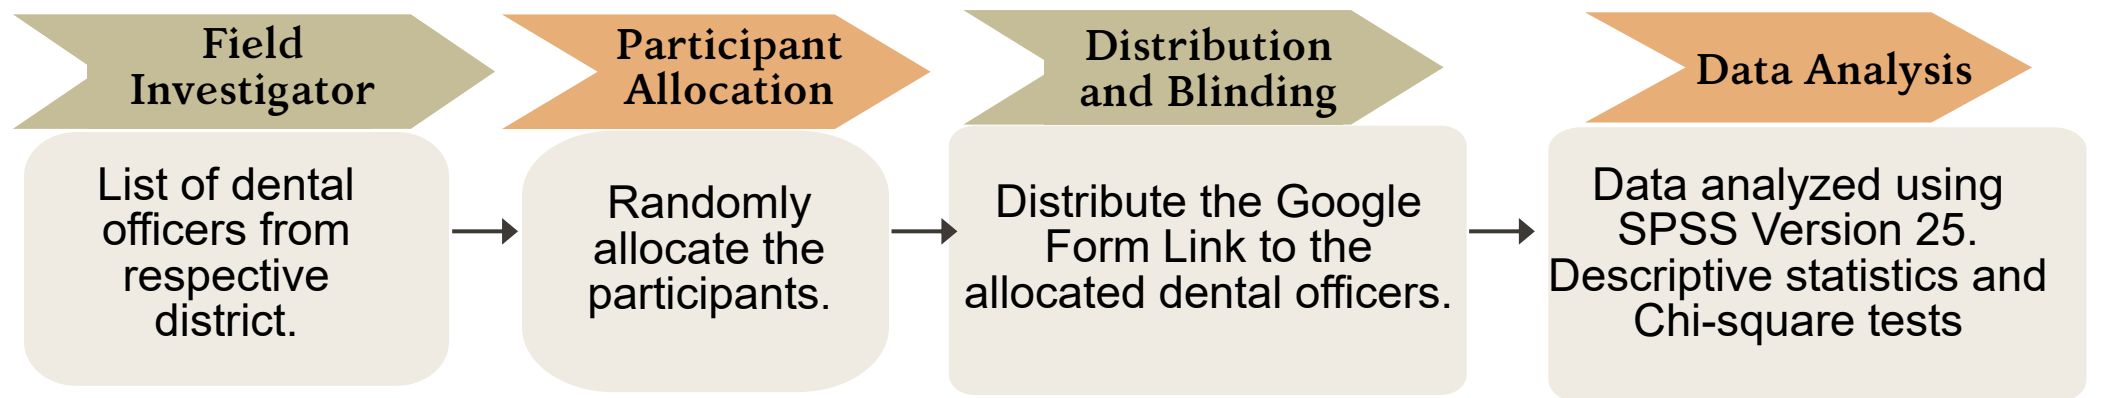

FIGURE 1 Process of Collecting the Data

RESULTS

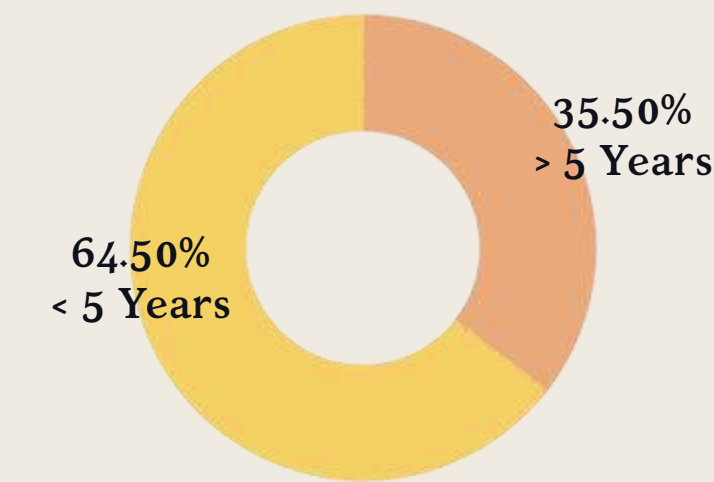

FIGURE 2 Distribution of Participants by Working Experience

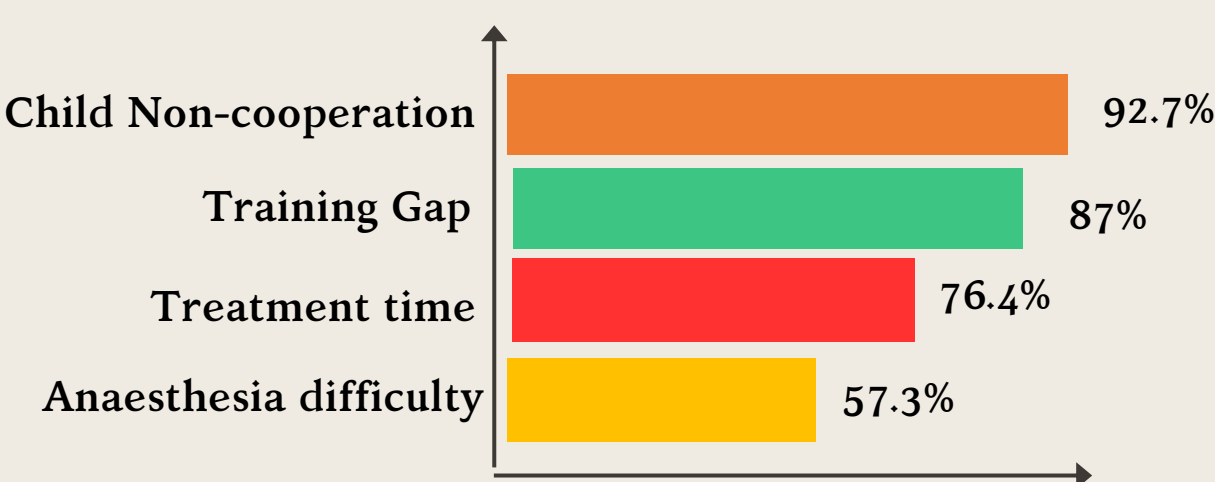

FIGURE 3 Perceived Barriers in Management of MIH

Perception		Percentage (%)
Diagnostic Confidence	Very Confident	3.3
	Confident	71.4
	Not Confident	25.3
Training Need	Yes	98.5
	No	1.5

TABLE 1 Key Findings on Perception Diagnostic Confidence and Training Need

Knowledge		Percentage (%)
Clinical Presentation	Yellow/Brown Demarcation	29.4
	Post-eruptive Breakdown	3.1
Preferred Treatment	Composite + GIC	48.7
	Composite Only	21.8
	GIC	16.0

TABLE 2 Key Findings on Operator’s Knowledge on Clinical Presentation of MIH and Preferred Treatment

DISCUSSION

Child non-cooperation and insufficient training were the main barriers to MIH management, consistent with previous studies.^{1,3} Despite generally high diagnostic confidence, gaps remained in recognising severe MIH features, highlighting areas for improvement in clinical practice.

CONCLUSION

- Good awareness of MIH among dental officers.
- Diagnostic confidence and clinical management require strengthening.
- Structured clinical training and continuing education are recommended.
